DUODENAL – ILEAL FISTULA, RARE VARIANT OF PENETRATING OF DUODENAL ULCER, ASSOCIATED WITH SIGMOID CANCER (Abstract): Duodeno-ileal fistula has benign (penetration of the duodenal ulcer) or malignant etiology. We present the case of a 73 years old woman, with history of right colectomy; she was admitted in our surgical unit for abdominal pain, fecaloid vomiting, fetid halitosis, bloody diarrhea, weight loss and impaired general condition. A moderate anemia and several electrolytic disorders have been revealed by the laboratory exams. The upper digestive endoscopy revealed a penetrating duodenal ulcer with duodeno-ileal fistula and colonoscopy a stenosing tumor at 25 cm of the anal edge. After the correction of anemia and electrolytic disorders an exploratory laparotomy was performed. The exploration noted a tumor mass which included duodenum and gastric antrum, gallbladder, ileum, sigmoid loop and the great omentum. The careful dissection confirmed the sigmoid cancer invading the antropyloric region and the double duodenal ulcer with pancreatic penetration and duodeno-ileal fistula. Multiple organs resection were performed: anterograde cholecystectomy; segmental enterectomy; ¾ distal gastric resection with precolic gastro-jejunal anastomosis (Leger type); sigmoid resection with end-to-end colo-colic anastomosis. The postoperative course was uneventful. Several data from the literature were discussed. CONCLUSIONS: Duodeno-ileal fistula is an accidental variety of ulcer penetration caused by particular morphopathological conditions. Surgical treatment of gastro-digestive fistulas should be applied early with a correct balancing of the patient. Operation is complex and often atypical and implies multiple organs resections. In this particular case, the sigmoid cancer which invaded the distal part of the stomach complicated much more the surgical procedure.

SHORT TITLE: Duodenal-ileal fistula & sigmoid cancer

INTRODUCTION
Penetration, complication of ulcer disease determine sometimes, adherence to a hollow organ. Through the inflammatory process and chlordih-peptic aggression, can occur internal fistulas [1]. Between them gastro-jejuno-colic fistula is classically noted [2-7]. Duodeno-ileal fistula is rarely reported.

CASE REPORT
A 73 years old woman was admitted to Municipal Hospital Dej, with abdominal pain, fecaloid vomiting, fetid halitosis,
bloody diarrhea, weight loss and impaired general condition. From she’s medical history we retained a right colic flexure neoplasm, 34 years ago, for which right hemicolectomy has been performed. Physical exam revealed a cachexia, an anxious facies with the palpebral edemas, pallor, hypotonic muscles and pretibial edema. The abdominal palpation revealed 10 x 10 cm painful mass, located in the superior right quadrant.

Abdominal ultrasound noted a colic thickness. The upper digestive endoscopy noted faeces into the stomach and two duodenal ulcers and raise the suspicion of duodeno-colic fistula. Colonoscopy revealed a hemorrhagic and stenotic tumor at 25 cm of the anal edge. Laboratory tests have shown elevated ESR (Erythrocytes Sedimentation Rate) (81 mm/1 h; 123 mm/2h), leucocytosis (WBC 12.20K/µL), moderate anemia (RBC 3.54M/µL, Haemoglobin (Hb) 9.6g/dL, Hematocrit (Ht)) 28.8%) and a hypoproteinemia (Total Proteins 5.2 g/dL) and several electrolytic disorders (Na⁺ 142 mmol/L; K⁺ 3.9 mmol/L; Ca²⁺ 8.37mg/dL; Mg²⁺ 1.91mg/dL). The CT scan and tumor markers were not performed for technical reasons.

After correction of anemia and serum electrolytes an exploratory laparotomy was performed. An iterative median laparotomy (right colectomy several years ago) was done. The exploration noted a tumor mass which included duodenum and gastric antrum, gallbladder, ileum, sigmoid loop and the great omentum. The careful dissection confirmed the sigmoid cancer invading the antropyloric region and double duodenal ulcer with pancreatic penetration and duodeno-ileal fistula (Fig. 1). We performed several resections in the following order: anterograde cholecystectomy; segmental enterectomy (upstream and downstream of the duodeno-ileal fistula); ¾ distal gastric resection with precolic gastro-jejunal anastomosis (Leger type); sigmoid resection with end-to-end colo-colic anastomosis (Fig. 2).

Postoperative treatment included blood transfusions, hydro-electrolyte and-acid base corrections, antibiotics, preventive antithrombotic treatment and proton pump inhibitors therapy. The postoperative follow up was uneventful with intestinal transit recovery after 72 hours. The patient was discharged in 11th postoperative day.

The histopathological exam revealed a colic adenocarcinoma with gastric invasion, pT₄N₀M₀ G₂. No venous, lymphatic emboli were noted neither perineural invasion. 12 lymph nodes were found and dissected on sigmoid resection specimen and no lymph nodes metastases were found.  

**DISCUSSION**  
In the case presented are associated two diseases with rare but explainable evolution: a sigmoid cancer with invasion of gastric antrum and a double ulcer complicated by posterior pancreatic penetration and duodeno-ileal fistula. A
Duodenal ileal fistula & sigmoid cancer

The exploratory laparotomy allowed the lesion inventory and correct diagnosis. The surgery procedure was challenged and imposed multiple visceral resections. The choice of digestive type reconstruction was logical in the context of lesions. We performed a gastro-jejunal anastomosis fashioned in precolic manner because the transverse mesocolic retraction [12]. We have preferred a gastro-jejunal end-to-side anastomosis instead of “Roux” gastro-jejunal anastomosis to short and simplify the procedure. The sigmoid resection was performed in usual manner but we preserved the superior left vessels to ensure a good vascular supply for the colon, given the antecedent of right colectomy. Despite the multiple organs resection, the postoperative course was uneventful.

The long term prognosis remains uncertain, given the disease stage and limited oncologic colic resection. Adjuvant chemotherapy is indicated but was refused by the patient. A colonoscopic control was provided one year after the procedure.

CONCLUSION
Duodeno-ileal fistula is an accidental variety of ulcer penetration caused by particular morphopathological conditions. Surgical treatment of gastro-digestive fistulas should be applied early with a correct balancing of the patient. Operation is complex and often atypical and implies multiple organs resections. In this particular case, the sigmoid cancer which invaded the distal part of the stomach complicated much more the surgical procedure. We were totally satisfied by the Leger type precolic gastrojejunostomy.
